Package 'ARDL'

January 10, 2021

Type Package

Title ARDL, ECM and Bounds-Test for Cointegration

Description Creates complex autoregressive distributed lag (ARDL) models providing just the order and automatically constructs the underlying unrestricted and restricted error correction model (ECM). It also performs the bounds-test for cointegration as described in Pesaran et al. (2001) <doi:10.1002/jae.616> and provides the multipliers and the cointegrating equation.

R topics documented:

`ardl` *ARDL model regression*

Description

A simple way to construct complex ARDL specifications providing just the model order additional to the model formula. It uses `dynlm` under the hood.

Usage

```
ardl(formula, data, order, start = NULL, end = NULL, ...)
```

Arguments

`formula`	A "formula" describing the linear model. Details for model specification are given under 'Details'.
`data`	A time series object (e.g., "ts", "zoo" or "zooreg") or a data frame containing the variables in the model. In the case of a data frame, it is coerced into a `ts` object with `start = 1`, `end = nrow(data)` and `frequency = 1`. If not found in data, the variables are NOT taken from any environment.
`order`	A specification of the order of the ARDL model. A numeric vector of the same length as the total number of variables (excluding the fixed ones, see 'Details'). It should only contain positive integers or 0. An integer could be provided if all variables are of the same order.
`start`	Start of the time period which should be used for fitting the model.
`end`	End of the time period which should be used for fitting the model.
`...`	Additional arguments to be passed to the low level regression fitting functions.

Details

The `formula` should contain only variables that exist in the data provided through `data` plus some additional functions supported by `dynlm` (i.e., `trend()`).

You can also specify fixed variables that are not supposed to be lagged (e.g. dummies etc.) simply by placing them after `|`. For example, `y ~ x1 + x2 | z1 + z2` where `z1` and `z2` are the fixed variables and should not be considered in `order`. Note that the `|` notion should not be confused with the same notion in `dynlm` where it introduces instrumental variables.

Value

ardl returns an object of class c("dynlm","lm","ardl"). In addition, attributes 'order', 'data', 'parsed_formula' and 'full_formula' are provided.

Mathematical Formula

The general form of an $ARDL(p, q_1, \ldots, q_k)$ is:

$$y_t = c_0 + c_1 t + \sum_{i=1}^{p} b_{y,i} y_{t-i} + \sum_{j=1}^{k} \sum_{l=0}^{q_j} b_{j,l} x_{j,t-l} + \epsilon_t$$

## Estimate an ARDL(3,1,3,2) model -------------------------------------

ardl_3132 <- ardl(LRM ~ LRY + IBO + IDE, data = denmark, order = c(3,1,3,2))
summary(ardl_3132)

## Add dummies or other variables that should stay fixed ---------------

d_74Q1_75Q3 <- ifelse(time(denmark) >= 1974 & time(denmark) <= 1975.5, 1, 0)

# the date can also be setted as below
d_74Q1_75Q3_ <- ifelse(time(denmark) >= "1974 Q1" & time(denmark) <= "1975 Q3", 1, 0)
identical(d_74Q1_75Q3, d_74Q1_75Q3_)
den <- cbind(denmark, d_74Q1_75Q3)
ardl_3132_d <- ardl(LRM ~ LRY + IBO + IDE | d_74Q1_75Q3,
                    data = den, order = c(3,1,3,2))
summary(ardl_3132_d)
compare <- data.frame(AIC = c(AIC(ardl_3132), AIC(ardl_3132_d)),
                      BIC = c(BIC(ardl_3132), BIC(ardl_3132_d)))
rownames(compare) <- c("no ummy", "with dummy")
compare

## Estimate an ARDL(3,1,3,2) model with a linear trend -----------------

ardl_3132_tr <- ardl(LRM ~ LRY + IBO + IDE + trend(LRM),
                     data = denmark, order = c(3,1,3,2))

# Alternative time trend specifications:
# time(LRM)                 1974 + (0, 1, ..., 55)/4 time(data)
```

```
# trend(LRM)                (1, 2, ..., 55)/4        (1:n)/freq
# trend(LRM, scale = FALSE) (1, 2, ..., 55)          1:n

## Subsample ARDL regression (start after 1975 Q4) ----------------------

ardl_3132_sub <- ardl(LRM ~ LRY + IBO + IDE, data = denmark,
                      order = c(3,1,3,2), start = "1975 Q4")

# the date can also be setted as below
ardl_3132_sub2 <- ardl(LRM ~ LRY + IBO + IDE, data = denmark,
                       order = c(3,1,3,2), start = c(1975,4))
identical(ardl_3132_sub, ardl_3132_sub2)
summary(ardl_3132_sub)

## Ease of use ------------------------------------------------------------

# The model specification of the ardl_3132 model can be created as easy as order=c(3,1,3,2)
# or else, it could be done using the dynlm package as:
library(dynlm)
m <- dynlm(LRM ~ L(LRM, 1) + L(LRM, 2) + L(LRM, 3) + LRY + L(LRY, 1) + IBO + L(IBO, 1) +
           L(IBO, 2) + L(IBO, 3) + IDE + L(IDE, 1) + L(IDE, 2), data = denmark)
identical(m$coefficients, ardl_3132$coefficients)

# The full formula can be extracted from the ARDL model, and this is equal to
ardl_3132$full_formula
m2 <- dynlm(ardl_3132$full_formula, data = ardl_3132$data)
identical(m$coefficients, m2$coefficients)
```

`auto_ardl` *Automatic ARDL model selection*

Description

It searches for the best ARDL order specification, according to the selected criterion, taking into account the constraints provided.

Usage

```
auto_ardl(
  formula,
  data,
  max_order,
  fixed_order = -1,
  starting_order = NULL,
  selection = "AIC",
  selection_minmax = c("min", "max"),
  grid = FALSE,
  search_type = c("horizontal", "vertical"),
  start = NULL,
```

```
  end = NULL,
  ...
)
```

Arguments

formula	A "formula" describing the linear model. Details for model specification are given under 'Details' in the help file of the ardl function.
data	A time series object (e.g., "ts", "zoo" or "zooreg") or a data frame containing the variables in the model. In the case of a data frame, it is coerced into a ts object with start = 1, end = nrow(data) and frequency = 1. If not found in data, the variables are NOT taken from any environment.
max_order	It sets the maximum order for each variable where the search is taking place. A numeric vector of the same length as the total number of variables (excluding the fixed ones, see 'Details' in the help file of the ardl function). It should only contain positive integers. An integer could be provided if the maximum order for all variables is the same.
fixed_order	It allows setting a fixed order for some variables. The algorithm will not search for any other order than this. A numeric vector of the same length as the total number of variables (excluding the fixed ones). It should contain positive integers or 0 to set as a constraint. A -1 should be provided for any variable that should not be constrained. fixed_order overrides the corresponding max_order and starting_order.
starting_order	Specifies the order for each variable from which each search will start. It is a numeric vector of the same length as the total number of variables (excluding the fixed ones). It should contain positive integers or 0 or only one integer could be provided if the starting order for all variables is the same. Default is set to NULL. If unspecified (NULL) and grid = FALSE, then all possible $ARDL(p)$ models are calculated (constraints are taken into account), where p is the minimum value in max_order. Note that where starting_order is provided, its first element will be the minimum value of p that the searching algorithm will consider (think of it like a 'minimum p order' restriction) (see 'Searching algorithm' below). If grid = TRUE, only the first argument (p) will have an effect.
selection	A character string specifying the selection criterion according to which the candidate models will be ranked. Default is AIC. Any other selection criterion can be used (a user specified or a function from another package) as long as it can be applied as selection(model). The preferred model is the one with the smaller value of the selection criterion. If the selection criterion works the other way around (the bigger the better), selection_minmax = "max" should also be supplied (see 'Examples' below).
selection_minmax	A character string that indicates whether the criterion in selection is supposed to be minimized (default) or maximized.
grid	If FALSE (default), the stepwise searching regression algorithm will search for the best model by adding and subtracting terms corresponding to different ARDL orders. If TRUE, the whole set of all possible ARDL models (accounting for constraints) will be evaluated. Note that this method can be very time-consuming in

case that max_order is big and there are many independent variables that create a very big number of possible combinations.

search_type — A character string describing the search type. If "horizontal" (default), the searching algorithm increases or decreases by 1 the order of each variable in each iteration. When the order of the last variable has been accessed, it begins again from the first variable until it converges. If "vertical", the searching algorithm increases or decreases by 1 the order of a variable until it converges. Then it continues the same for the next variable. The two options result to very similar top orders. The default ("horizontal"), sometimes is a little more accurate, but the "vertical" is almost 2 times faster. Not applicable if grid = TRUE.

start — Start of the time period which should be used for fitting the model.

end — End of the time period which should be used for fitting the model.

... — Additional arguments to be passed to the low level regression fitting functions.

Value

auto_ardl returns a list which contains:

best_model — An object of class c("dynlm","lm","ardl")

best_order — A numeric vector with the order of the best model selected

top_orders — A data.frame with the orders of the top 20 models

Searching algorithm

The algorithm performs the optimization process starting from multiple starting points concerning the autoregressive order p. The searching algorithm will perform a complete search, each time starting from a different starting order. These orders are presented in the tables below, for grid = FALSE and different values of starting_order.

starting_order = NULL:

ARDL(p)	->	p	q1	q2	...	qk
ARDL(1)	->	1	1	1	...	1
ARDL(2)	->	2	2	2	...	2
:	->	:	:	:	:	:
ARDL(P)	->	P	P	P	...	P

starting_order = c(3,0,1,2):

p	q1	q2	q3
3	0	1	2
4	0	1	2
:	:	:	:
P	0	1	2

bounds_f_test *Bounds Wald-test for no cointegration*

Description

bounds_f_test performs the Wald bounds-test for no cointegration *Pesaran et al. (2001).* It is a Wald test on the parameters of a UECM (Unrestricted Error Correction Model) expressed either as a Chisq-statistic or as an F-statistic.

Usage

```
bounds_f_test(
  object,
  case,
  alpha = NULL,
  pvalue = TRUE,
  exact = FALSE,
  R = 40000,
  test = c("F", "Chisq"),
  vcov_matrix = NULL
)
```

Arguments

object	An object of class 'ardl' or 'uecm'.
case	An integer from 1-5 or a character string specifying whether the 'intercept' and/or the 'trend' have to participate in the short-run or the long-run relationship (cointegrating equation) (see section 'Cases' below).
alpha	A numeric value between 0 and 1 indicating the significance level of the critical value bounds. If NULL (default), no critical value bounds for a specific level of significance are provide, only the p-value. See section 'alpha, bounds and p-value' below for details.
pvalue	A logical indicating whether you want the p-value to be provided. The default is TRUE. See section 'alpha, bounds and p-value' below for details.
exact	A logical indicating whether you want asymptotic (T = 1000) or exact sample size critical value bounds and p-value. The default is FALSE for asymptotic. See section 'alpha, bounds and p-value' below for details.
R	An integer indicating how many iterations will be used if exact = TRUE. Default is 40000.
test	A character vector indicating whether you want the Wald test to be expressed as 'F' or as 'Chisq' statistic. Default is "F".

vcov_matrix — The estimated covariance matrix of the random variable that the test uses to estimate the test statistic. The default is vcov(object) (when vcov_matrix = NULL), but other estimations of the covariance matrix of the regression's estimated coefficients can also be used (e.g., using vcovHC or vcovHAC). Only applicable if the input object is of class "uecm".

Value

A list with class "htest" containing the following components:

method	a character string indicating what type of test was performed.
alternative	a character string describing the alternative hypothesis.
statistic	the value of the test statistic.
null.value	the value of the population parameters k (the number of independent variables) and T (the number of observations) specified by the null hypothesis.
data.name	a character string giving the name(s) of the data.
parameters	numeric vector containing the critical value bounds.
p.value	the p-value of the test.
tab	data.frame containing the statistic, the critical value bounds, the alpha level of significance and the p-value.

Hypothesis testing

$$\Delta y_t = c_0 + c_1 t + \pi_y y_{t-1} + \sum_{j=1}^{k} \pi_j x_{j,t-1} + \sum_{i=1}^{p-1} \psi_{y,i} \Delta y_{t-i} + \sum_{j=1}^{k} \sum_{l=1}^{q_j - 1} \psi_{j,l} \Delta x_{j,t-l} + \sum_{j=1}^{k} \omega_j \Delta x_{j,t} + \epsilon_t$$

Cases 1, 3, 5:

$$\mathbf{H_0}: \pi_y = \pi_1 = \ldots = \pi_k = 0$$

$$\mathbf{H_1}: \pi_y \neq \pi_1 \neq \ldots \neq \pi_k \neq 0$$

Case 2:

$$\mathbf{H_0}: \pi_y = \pi_1 = \ldots = \pi_k = c_0 = 0$$

$$\mathbf{H_1}: \pi_y \neq \pi_1 \neq \ldots \neq \pi_k \neq c_0 \neq 0$$

Case 4:

$$\mathbf{H_0}: \pi_y = \pi_1 = \ldots = \pi_k = c_1 = 0$$

$$\mathbf{H_1}: \pi_y \neq \pi_1 \neq \ldots \neq \pi_k \neq c_1 \neq 0$$

alpha, bounds and p-value

In this section it is explained how the critical value bounds and p-values are obtained.

- If `exact = FALSE`, then the asymptotic (T = 1000) critical value bounds and p-value are provided.
- Only the asymptotic critical value bounds and p-values, and only for k <= 10 are precalculated, everything else has to be computed.
- Precalculated critical value bounds and p-values were simulated using `set.seed(2020)` and `R = 70000`.
- Precalculated critical value bounds exist only for `alpha` being one of the 0.005, 0.01, 0.025, 0.05, 0.075, 0.1, 0.15 or 0.2, everything else has to be computed.
- If `alpha` is one of the 0.1, 0.05, 0.025 or 0.01 (and `exact = FALSE` and k <= 10), the critical value bounds are those presented in *Pesaran et al. (2001)*.

Cases

According to *Pesaran et al. (2001)*, we distinguish the long-run relationship (cointegrating equation) (and thus the bounds-test and the Restricted ECMs) between 5 different cases. These differ in terms of whether the 'intercept' and/or the 'trend' are restricted to participate in the long-run relationship or they are unrestricted and so they participate in the short-run relationship.

Case 1:
- No *intercept* and no *trend*.
- `case` inputs: 1 or "n" where "n" stands for none.

Case 2:
- Restricted *intercept* and no *trend*.
- `case` inputs: 2 or "rc" where "rc" stands for restricted constant.

Case 3:
- Unrestricted *intercept* and no *trend*.
- `case` inputs: 3 or "uc" where "uc" stands for unrestricted constant.

Case 4:
- Unrestricted *intercept* and restricted *trend*.
- `case` inputs: 4 or "ucrt" where "ucrt" stands for unrestricted constant and restricted trend.

Case 5:
- Unrestricted *intercept* and unrestricted *trend*.
- `case` inputs: 5 or "ucut" where "ucut" stands for unrestricted constant and unrestricted trend.

Note that you can't restrict (or leave unrestricted) a parameter that doesn't exist in the input model. For example, you can't compute `recm(object,case=3)` if the object is an ARDL (or UECM) model with no intercept. The same way, you can't compute `bounds_f_test(object,case=5)` if the object is an ARDL (or UECM) model with no linear trend.

# (unrestricted constant and unrestricted trend)
bounds_f_test(ardl_3132_ct, case = "ucut")
# or
bounds_f_test(ardl_3132_ct, case = 5)
```

```
## Note that you can't restrict a deterministic term that doesn't exist

# For example, the following tests will produce an error:
## Not run:
bounds_f_test(ardl_3132_c, case = 1)
bounds_f_test(ardl_3132_ct, case = 3)
bounds_f_test(ardl_3132_c, case = 4)

## End(Not run)

## Asymptotic p-value and critical value bounds (assuming T = 1000) ----

# Include critical value bounds for a certain level of significance

# F-statistic is larger than the I(1) bound (for a=0.05) as expected (p-value < 0.05)
bft <- bounds_f_test(ardl_3132_c, case = 2, alpha = 0.05)
bft
bft$tab

# F-statistic is slightly larger than the I(1) bound (for a=0.005)
# as p-value is slightly smaller than 0.005
bounds_f_test(ardl_3132_c, case = 2, alpha = 0.005)

## Exact sample size p-value and critical value bounds -----------------

# Setting a seed is suggested to allow the replication of results
# 'R' can be increased for more accurate resutls

# F-statistic is smaller than the I(1) bound (for a=0.01) as expected (p-value > 0.01)
# Note that the exact sample p-value (0.01285) is very different than the asymptotic (0.004418)
# It can take more than 30 seconds
## Not run:
set.seed(2020)
bounds_f_test(ardl_3132_c, case = 2, alpha = 0.01, exact = TRUE)

## End(Not run)

## "F" and "Chisq" statistics ----------------------------------------

# The p-value is the same, the test-statistic and critical value bounds are different but analogous
bounds_f_test(ardl_3132_c, case = 2, alpha = 0.01)
bounds_f_test(ardl_3132_c, case = 2, alpha = 0.01, test = "Chisq")
```

---

bounds_t_test *Bounds t-test for no cointegration*

Description

bounds_t_test performs the t-bounds test for no cointegration *Pesaran et al. (2001).* It is a t-test on the parameters of a UECM (Unrestricted Error Correction Model).

Usage

```
bounds_t_test(
  object,
  case,
  alpha = NULL,
  pvalue = TRUE,
  exact = FALSE,
  R = 40000,
  vcov_matrix = NULL
)
```

Arguments

object	An object of class 'ardl' or 'uecm'.
case	An integer (1, 3 or 5) or a character string specifying whether the 'intercept' and/or the 'trend' have to participate in the short-run relationship (see section 'Cases' below). Note that the t-bounds test can't be applied for cases 2 and 4.
alpha	A numeric value between 0 and 1 indicating the significance level of the critical value bounds. If NULL (default), no critical value bounds for a specific level of significance are provide, only the p-value. See section 'alpha, bounds and p-value' below for details.
pvalue	A logical indicating whether you want the p-value to be provided. The default is TRUE. See section 'alpha, bounds and p-value' below for details.
exact	A logical indicating whether you want asymptotic (T = 1000) or exact sample size critical value bounds and p-value. The default is FALSE for asymptotic. See section 'alpha, bounds and p-value' below for details.
R	An integer indicating how many iterations will be used if exact = TRUE. Default is 40000.
vcov_matrix	The estimated covariance matrix of the random variable that the test uses to estimate the test statistic. The default is vcov(object) (when vcov_matrix = NULL), but other estimations of the covariance matrix of the regression's estimated coefficients can also be used (e.g., using vcovHC or vcovHAC). Only applicable if the input object is of class "uecm".

Value

A list with class "htest" containing the following components:

method	a character string indicating what type of test was performed.
alternative	a character string describing the alternative hypothesis.
statistic	the value of the test statistic.
null.value	the value of the population parameters k (the number of independent variables) and T (the number of observations) specified by the null hypothesis.
data.name	a character string giving the name(s) of the data.
parameters	numeric vector containing the critical value bounds.

p.value	the p-value of the test.
tab	data.frame containing the statistic, the critical value bounds, the alpha level of significance and the p-value.

Hypothesis testing

$$\Delta y_t = c_0 + c_1 t + \pi_y y_{t-1} + \sum_{j=1}^{k} \pi_j x_{j,t-1} + \sum_{i=1}^{p-1} \psi_{y,i} \Delta y_{t-i} + \sum_{j=1}^{k} \sum_{l=1}^{q_j - 1} \psi_{j,l} \Delta x_{j,t-l} + \sum_{j=1}^{k} \omega_j \Delta x_{j,t} + \epsilon_t$$

$$\mathbf{H_0} : \pi_y = 0$$

$$\mathbf{H_1} : \pi_y \neq 0$$

alpha, bounds and p-value

In this section it is explained how the critical value bounds and p-values are obtained.

- If `exact = FALSE`, then the asymptotic (T = 1000) critical value bounds and p-value are provided.
- Only the asymptotic critical value bounds and p-values, and only for k <= 10 are precalculated, everything else has to be computed.
- Precalculated critical value bounds and p-values were simulated using `set.seed(2020)` and `R = 70000`.
- Precalculated critical value bounds exist only for `alpha` being one of the 0.005, 0.01, 0.025, 0.05, 0.075, 0.1, 0.15 or 0.2, everything else has to be computed.
- If `alpha` is one of the 0.1, 0.05, 0.025 or 0.01 (and `exact = FALSE` and k <= 10), the critical value bounds are those presented in *Pesaran et al. (2001)*.

Cases

According to *Pesaran et al. (2001)*, we distinguish the long-run relationship (cointegrating equation) (and thus the bounds-test and the Restricted ECMs) between 5 different cases. These differ in terms of whether the 'intercept' and/or the 'trend' are restricted to participate in the long-run relationship or they are unrestricted and so they participate in the short-run relationship.

Case 1:
- No *intercept* and no *trend*.
- `case` inputs: 1 or "n" where "n" stands for none.

Case 2:
- Restricted *intercept* and no *trend*.
- `case` inputs: 2 or "rc" where "rc" stands for restricted constant.

Case 3:
- Unrestricted *intercept* and no *trend*.
- `case` inputs: 3 or "uc" where "uc" stands for unrestricted constant.

Case 4:
- Unrestricted *intercept* and restricted *trend*.
- `case` inputs: 4 or "ucrt" where "ucrt" stands for unrestricted constant and restricted trend.

Case 5:
- Unrestricted *intercept* and unrestricted *trend*.
- `case` inputs: 5 or "ucut" where "ucut" stands for unrestricted constant and unrestricted trend.

Note that you can't restrict (or leave unrestricted) a parameter that doesn't exist in the input model. For example, you can't compute `recm(object,case=3)` if the object is an ARDL (or UECM) model with no intercept. The same way, you can't compute `bounds_f_test(object,case=5)` if the object is an ARDL (or UECM) model with no linear trend.

```

`coint_eq` *Cointegrating equation (long-run level relationship)*

Description

Creates the cointegrating equation (long-run level relationship) providing an 'ardl', 'uecm' or 'recm' model.

Usage

```
coint_eq(object, case)
```

```
## S3 method for class 'recm'
coint_eq(object, ...)

## Default S3 method:
coint_eq(object, case)
```

Arguments

object	An object of class 'ardl', 'uecm' or 'recm'.
case	An integer from 1-5 or a character string specifying whether the 'intercept' and/or the 'trend' have to participate in the long-run level relationship (cointegrating equation) (see section 'Cases' below). If the input object is of class 'recm', case is not needed as the model is already under a certain case.
...	Currently unused argument.

Value

coint_eq returns an numeric vector containing the cointegrating equation.

Cases

According to *Pesaran et al. (2001)*, we distinguish the long-run relationship (cointegrating equation) (and thus the bounds-test and the Restricted ECMs) between 5 different cases. These differ in terms of whether the 'intercept' and/or the 'trend' are restricted to participate in the long-run relationship or they are unrestricted and so they participate in the short-run relationship.

Case 1:
- No *intercept* and no *trend*.
- case inputs: 1 or "n" where "n" stands for none.

Case 2:
- Restricted *intercept* and no *trend*.
- case inputs: 2 or "rc" where "rc" stands for restricted constant.

Case 3:
- Unrestricted *intercept* and no *trend*.
- case inputs: 3 or "uc" where "uc" stands for unrestricted constant.

Case 4:
- Unrestricted *intercept* and restricted *trend*.
- case inputs: 4 or "ucrt" where "ucrt" stands for unrestricted constant and restricted trend.

Case 5:
- Unrestricted *intercept* and unrestricted *trend*.
- case inputs: 5 or "ucut" where "ucut" stands for unrestricted constant and unrestricted trend.

Note that you can't restrict (or leave unrestricted) a parameter that doesn't exist in the input model. For example, you can't compute recm(object,case=3) if the object is an ARDL (or UECM) model with no intercept. The same way, you can't compute bounds_f_test(object,case=5) if the object is an ARDL (or UECM) model with no linear trend.

denmark *The Danish data on money income prices and interest rates*

Description

This data set contains the series used by S. Johansen and K. Juselius for estimating a money demand function of Denmark.

Usage

```
denmark
```

Format

A data frame with 55 rows and 5 variables. Time period from 1974:Q1 until 1987:Q3.

LRM logarithm of real money, M2

LRY logarithm of real income

LPY logarithm of price deflator

IBO bond rate

IDE bank deposit rate

Details

An object of class "zooreg" "zoo".

multipliers *Multipliers estimation*

Description

multipliers is a generic function used to estimate short-run (impact), interim and long-run (total) multipliers, along with their corresponding standard errors, t-statistics and p-values.

Usage

```
multipliers(object, type = "lr", vcov_matrix = NULL)

## S3 method for class 'ardl'
multipliers(object, type = "lr", vcov_matrix = NULL)

## S3 method for class 'uecm'
multipliers(object, type = "lr", vcov_matrix = NULL)
```

Arguments

object	An object of class 'ardl' or 'uecm'.
type	A character string describing the type of multipliers. Use "lr" for long-run (total) multipliers (default), "sr" or 0 for short-run (impact) multipliers or an integer between 1 and 100 for interim multipliers.
vcov_matrix	The estimated covariance matrix of the random variable that the transformation function uses to estimate the standard errors (and so the t-statistics and p-values) of the multipliers. The default is vcov(object) (when vcov_matrix = NULL), but other estimations of the covariance matrix of the regression's estimated coefficients can also be used (e.g., using vcovHC or vcovHAC).

Details

The function invokes two different methods, one for objects of class 'ardl' and one for objects of class 'uecm'. This is because of the different (but equivalent) transformation functions that are used for each class/model ('ardl' and 'uecm') to estimate the multipliers.

Note that type = 0 is equivalent to type = "sr". Also, type = s will produce the same estimates as type = "lr" for those particular variable for which s >= from their ARDL order.

The delta method is used for approximating the standard errors (and thus the t-statistics and p-values) of the estimated multipliers.

Value

multipliers returns a data.frame containing the independent variables (including possibly existing intercept or trend and excluding the fixed variables) and their corresponding standard errors, t-statistics and p-values.

Mathematical Formula

Constant and Linear Trend:

As derived from an ARDL:

$$\mu = \frac{c_0}{1 - \sum_{i=1}^{p} b_{y,i}}$$

$$\delta = \frac{c_1}{1 - \sum_{i=1}^{p} b_{y,i}}$$

As derived from an Unrestricted ECM:

$$\mu = \frac{c_0}{-\pi_y}$$

$$\delta = \frac{c_1}{-\pi_y}$$

Short-Run Multipliers:

As derived from an ARDL:

$$\frac{\partial y_t}{\partial x_{j,t}} = \frac{b_{j,0}}{1 - \sum_{i=1}^{p} b_{y,i}} \quad \forall j = 1, \ldots, k$$

As derived from an Unrestricted ECM:

$$\frac{\partial y_t}{\partial x_{j,t}} = \frac{\omega_j}{-\pi_y} \quad \forall j = 1, \ldots, k$$

Interim Multipliers:

As derived from an ARDL:

$$\frac{\partial y_{t+s}}{\partial x_{j,t}} = \frac{\sum_{l=1}^{s} b_{j,l}}{1 - \sum_{i=1}^{p} b_{y,i}} \quad \forall j = 1, \ldots, k \quad s \in \{0, \ldots, q_j\}$$

As derived from an Unrestricted ECM:

$$\frac{\partial y_{t+s}}{\partial x_{j,t}} = \frac{\pi_j + \psi_{j,s}}{-\pi_y} \quad \forall j = 1, \ldots, k \quad s \in \{1, \ldots, q_j - 1\}$$

Long-Run Multipliers:

As derived from an ARDL:

$$\frac{\partial y_{t+\infty}}{\partial x_{j,t}} = \theta_j = \frac{\sum_{l=0}^{q_j} b_{j,l}}{1 - \sum_{i=1}^{p} b_{y,i}} \quad \forall j = 1, \ldots, k$$

As derived from an Unrestricted ECM:

$$\frac{\partial y_{t+\infty}}{\partial x_{j,t}} = \theta_j = \frac{\pi_j}{-\pi_y} \quad \forall j = 1, \ldots, k$$

recm *Restricted ECM regression*

Description

Creates the Restricted Error Correction Model (RECM). This is the conditional RECM, which is the RECM of the underlying ARDL.

Usage

```
recm(object, case)
```

Arguments

`object`	An object of `class` 'ardl' or 'uecm'.
`case`	An integer from 1-5 or a character string specifying whether the 'intercept' and/or the 'trend' have to participate in the short-run or the long-run relationship (cointegrating equation) (see section 'Cases' below).

Details

Note that the statistical significance of 'L(ect, 1)' in a RECM should not be tested using the corresponding t-statistic (or the p-value) because it doesn't follow a standard t-distribution. Instead, the `bounds_t_test` should be used.

Value

`recm` returns an object of `class` `c("dynlm","lm","recm")`. In addition, attributes 'order', 'data', 'parsed_formula' and 'full_formula' are provided.

Mathematical Formula

The formula of a Restricted ECM conditional to an $ARDL(p, q_1, \ldots, q_k)$ is:

$$\Delta y_t = c_0 + c_1 t + \sum_{i=1}^{p-1} \psi_{y,i} \Delta y_{t-i} + \sum_{j=1}^{k} \sum_{l=1}^{q_j - 1} \psi_{j,l} \Delta x_{j,t-l} + \sum_{j=1}^{k} \omega_j \Delta x_{j,t} + \pi_y ECT_t + \epsilon_t$$

Under Case 1:
- $c_0 = c_1 = 0$
- $ECT = y_{t-1} - (\sum_{j=1}^{k} \theta_j x_{j,t-1})$

Under Case 2:
- $c_0 = c_1 = 0$
- $ECT = y_{t-1} - (\mu + \sum_{j=1}^{k} \theta_j x_{j,t-1})$

Under Case 3:
- $c_1 = 0$
- $ECT = y_{t-1} - (\sum_{j=1}^{k} \theta_j x_{j,t-1})$

Under Case 4:
- $c_1 = 0$
- $ECT = y_{t-1} - (\delta(t-1) + \sum_{j=1}^{k} \theta_j x_{j,t-1})$

Under Case 5:
- $ECT = y_{t-1} - (\sum_{j=1}^{k} \theta_j x_{j,t-1})$

Cases

According to *Pesaran et al. (2001)*, we distinguish the long-run relationship (cointegrating equation) (and thus the bounds-test and the Restricted ECMs) between 5 different cases. These differ in terms of whether the 'intercept' and/or the 'trend' are restricted to participate in the long-run relationship or they are unrestricted and so they participate in the short-run relationship.

Case 1:
- No *intercept* and no *trend*.
- `case` inputs: 1 or "n" where "n" stands for none.

Case 2:
- Restricted *intercept* and no *trend*.
- `case` inputs: 2 or "rc" where "rc" stands for restricted constant.

Case 3:
- Unrestricted *intercept* and no *trend*.
- `case` inputs: 3 or "uc" where "uc" stands for unrestricted constant.

Case 4:
- Unrestricted *intercept* and restricted *trend*.
- `case` inputs: 4 or "ucrt" where "ucrt" stands for unrestricted constant and restricted trend.

Case 5:
- Unrestricted *intercept* and unrestricted *trend*.
- `case` inputs: 5 or "ucut" where "ucut" stands for unrestricted constant and unrestricted trend.

Note that you can't restrict (or leave unrestricted) a parameter that doesn't exist in the input model. For example, you can't compute `recm(object,case=3)` if the object is an ARDL (or UECM) model with no intercept. The same way, you can't compute `bounds_f_test(object,case=5)` if the object is an ARDL (or UECM) model with no linear trend.

uecm *Unrestricted ECM regression*

Description

uecm is a generic function used to construct Unrestricted Error Correction Models (UECM). The function invokes two different methods. The default method works exactly like ardl. The other method requires an object of class 'ardl'. Both methods create the conditional UECM, which is the UECM of the underlying ARDL.

Usage

```
uecm(...)

## S3 method for class 'ardl'
uecm(object, ...)

## Default S3 method:
uecm(formula, data, order, start = NULL, end = NULL, ...)
```

Arguments

...	Additional arguments to be passed to the low level regression fitting functions.
object	An object of class 'ardl'.
formula	A "formula" describing the linear model. Details for model specification are given under 'Details'.
data	A time series object (e.g., "ts", "zoo" or "zooreg") or a data frame containing the variables in the model. In the case of a data frame, it is coerced into a ts object with start = 1, end = nrow(data) and frequency = 1. If not found in data, the variables are NOT taken from any environment.
order	A specification of the order of the underlying ARDL model (e.g., for the UECM of an ARDL(1,0,2) model it should be order = c(1,0,2)). A numeric vector of the same length as the total number of variables (excluding the fixed ones, see 'Details'). It should only contain positive integers or 0. An integer could be provided if all variables are of the same order.

start	Start of the time period which should be used for fitting the model.
end	End of the time period which should be used for fitting the model.

Details

The formula should contain only variables that exist in the data provided through data plus some additional functions supported by dynlm (i.e., trend()).

You can also specify fixed variables that are not supposed to be lagged (e.g. dummies etc.) simply by placing them after |. For example, y ~ x1 + x2 | z1 + z2 where z1 and z2 are the fixed variables and should not be considered in order. Note that the | notion should not be confused with the same notion in dynlm where it introduces instrumental variables.

Value

uecm returns an object of class c("dynlm","lm","uecm"). In addition, attributes 'order', 'data', 'parsed_formula' and 'full_formula' are provided.

Mathematical Formula

The formula of an Unrestricted ECM conditional to an $ARDL(p, q_1, \ldots, q_k)$ is:

$$\Delta y_t = c_0 + c_1 t + \pi_y y_{t-1} + \sum_{j=1}^{k} \pi_j x_{j,t-1} + \sum_{i=1}^{p-1} \psi_{y,i} \Delta y_{t-i} + \sum_{j=1}^{k} \sum_{l=1}^{q_j - 1} \psi_{j,l} \Delta x_{j,t-l} + \sum_{j=1}^{k} \omega_j \Delta x_{j,t} + \epsilon_t$$
