# The Tomato example: illustrating the smoothing and extraction of traits (SET) using growthPheno Version 2.x

### Chris Brien

### 24 July, 2024

This vignette illustrates the use of the two growthPheno (Brien, 2024) wrapper functions traitSmooths and traitExtractFeatures that are key to carrying out the smoothing and extracting traits (SET) method described by Brien et al. (2020). The Tomato example, used here, is the example that Brien et al. (2020) used to illustrate the SET method. More details on the rationale for this method are available in Brien et al. (2020, Methods section).

Here, the process has been modified from that described in the paper to take advantage of the new wrapper functions and other new capabilities that have been built into in Version 2.x of growthPheno. In particular, both natural cubic smoothing splines (NCSS) and P-splines (PS) are investigated for smoothing not only the Projected Shoot Area (PSA), but also the Water Use (WU). A segmented smooth, as suggested in Brien et al. (2020), is used to allow for a discontinuity in the growth resulting from unintentional, restricted watering for three days following imaging on DAP 39.

Two different approaches are shown for smoothing the two traits:

- **PSA:** For this trait, we first use traitSmooths to compare several smooths using logarithmic smoothing and then automatically choose a P-spline smooth whose lamda value is in the middle of the values for which smooths have been obtained. This is then followed by a comparison of two contending smooths. Finally, the chosen smooth is extracted and added to the data.
- WU: A more time-efficient approach is taken with this trait. First several direct smooths are compared and stored. Then plots of two contending smooths amongst the stored smooths are compared. Finally the chosen smooth is extracted from the stored smooths.

### Initialize

#### Set up characters for variable names and titles

### Step I: Import the longitudinal data

In this step, the aim is to produce the data.frame longi.dat that contains the imaging variables, covariates and factors for the experiment.

#### Load the pre-prepared data

data(tomato.dat)

Copy the data to preserve the original data.frame

longi.dat <- tomato.dat</pre>

# Step II: Investigate the smoothing of the PSA and obtain growth rates

The growth rates are the Absolute Growth Rate (AGR) and the Relative Growth Rate (RGR) for the PSA, which must be calculated from the observed data by differencing consecutive observations for a plant. They will also be calculated from the smoothed traits by differencing, although growthPheno can also obtain growth rates using the first derivatives of the smooths.

#### Fit three-parameter logistic curves logistic curves to compare with spline curves

We fit a three-parameter logistic curve, using nlme (Pinheiro J., Bates D., and R Core Team, 2023), as an alternative to spline smoothing.

Organize non-missing data into a grouped object

Fit logistics to individuals and obtain fitted values

```
logist.lis <- nlme::nlsList(SSlogis, logist.grp)
logist.dat$sPSA <- fitted(logist.lis)
logist.dat <- cbind(Tuning = factor("Logistic"), logist.dat)</pre>
```

### Compute smooths and growth rates of the PSA for a range of smoothing parameters

We begin by using the function traitSmooth to investigate a set of smooths for the PSA, employing all five traitSmooth steps of (i) Smooth, (ii) Profile plots, (iii) Median deviations plots, (iv) Choose a smooth, and (v) Chosen smooth plot. The only changes to the defaults for these five steps are to the df values that are investigated and to specify segmented smoothing. This includes allowing traitSmooth to choose automatically a single smooth as the chosen smooth. A segmented smooth involving two segments has also been specified, as suggested by Brien et al. (2020). The breakpoint for the segments is DAP 39, it coinciding with the start of an unintentional, three-day restriction in the watering; thus, the segments consist of DAP 18–39 and DAP 40–51. The growth rates are calculated, by default, from both the unsmoothed trait PSA and the smoothed trait sPSA by difference, rather than from the spline derivatives. Thus, the growth rate calculation for the smoothed data matches that which is obligatory for the observed data. Also, three-parameter logistic curves are fitted to the data using the R package nlme and growth rates calculated for it. The default layouts of the three sets of plots produced are mdoffied using the three arguments profile.plot.args, meddevn.plot.args and chosen.plot.args.

It is noted that the plots that are produced show that the logistic would not be an adequate fit for this data, especially after DAP 42.

```
suppressWarnings(
  longi.dat <- traitSmooth(data = tomato.dat,</pre>
                           response = "PSA", response.smoothed = "sPSA",
                           individuals = "Snapshot.ID.Tag", times = "DAP",
                           keep.columns = c("AMF","Zn"),
                           smoothing.args = args4smoothing(df = c(4:6,12),
                                                            smoothing.segments = DAP.segs,
                                                            external.smooths = logist.dat),
                           profile.plot.args =
                              args4profile_plot(facet.y = "AMF",
                                                colour.column = "Zn",
                                                facet.labeller = labeller(AMF = labelAMF)),
                           meddevn.plot.args =
                              args4meddevn_plot(facet.y = "AMF",
                                                facet.labeller = labeller(AMF = labelAMF)),
                           chosen.plot.args =

                                               ggplotFuncs = vline.DAP.endpts),
                           mergedata = tomato.dat))
```

DAP

# Compare log smoothing of PSA for NCSS with DF = 6 and PS with lambda = 1

Now compare what appear to be the best smooths for natural cubic smoothing splines (NCSS-df-6) and P-splines (PS-lambda-1) using traitSmooth. This is done by supplying smoothing.args with a list of parallel vectors, each vector being of length two. The argument chosen.smooth.args is set to NULL so that one of the smooths is not chosen for output. Again, arguments are included to control the smoothing and the layout of the profile and median-deviations plots.

Smoothing based on P-splines is chosen because it tends to smooth somewhat more than that based on NCSS splines, especially after DAP 45. Consequently, there is no need to change the values of the chosen.splines argument from the default values.

facet.x = tune.fac, facet.y = "AMF", facet.labeller = labeller(AMF = labelAMF), colour.column = "AMF"), meddevn.plot.args = args4meddevn\_plot(plots.by = NULL, plots.group = tune.fac, facet.x = ".", facet.y = "AMF", facet.labeller = labeller(AMF = labelAMF)))

## Warning: Removed 2 rows containing missing values or values outside the scale range
## ('geom\_line()').

## Warning: Removed 4 rows containing missing values or values outside the scale range
## ('geom\_point()').

## Warning: Removed 2 rows containing missing values or values outside the scale range
## ('geom\_line()').

## Removed 4 rows containing missing values or values outside the scale range
## ('geom\_point()').

Extract the chosen smooth, adding it to longi.dat

# Step III: Investigate the smoothing of the WU

# Explore the smooths of WU for a range of smoothing parameters

For WU, we take a slightly different approach to that taken with PSA. We first examine the fits for a range of smoothing parameters, setting the traitSmooth argument chosen.smooth.args to NULL so that a single

smooth is not chosen for output. We then examine the two smooths that are the main contenders and finally do plots for the smooth chosen from these two. Again, a segmented smooth involving two segments has also been specified with the breakpoint for the segments being DAP 39.

The function traitSmooth is used to produce the smooths. However, because no chosen.smooth.args is being specified, the function probeSmooths could be called directly instead. In this case, the get.rates and trait.types arguments from probeSmooths are set to FALSE and to "response" so that only the response is smoothed, without the calculation of growth rates from the smoothed response.

```
suppressWarnings(
  smth.dat <- traitSmooth(data = longi.dat,</pre>
                          response = "WU", response.smoothed = "sWU",
                          individuals = "Snapshot.ID.Tag", times = "DAP",
                          keep.columns = c("AMF","Zn"),
                          trait.types = "response",
                          smoothing.args =
                            args4smoothing(smoothing.methods = "direct",
                                            smoothing.segments = DAP.segs),
                          chosen.smooth.args = NULL,
                          profile.plot.args =
                            args4profile_plot(plots.by = NULL,
                                               facet.y = "AMF",
                                               colour.column = "Zn",
                                               facet.labeller = labeller(AMF = labelAMF)),
                          meddevn.plot.args =
                            args4meddevn_plot(plots.by = NULL,
                                               facet.y = "AMF",
                                               facet.labeller = labeller(AMF = labelAMF))))
```

# Produce plots comparing direct smoothing of WU for NCSS with DF = 6 and PS with lambda = 0.316

Now compare what appear to be the best smooths for natural cubic smoothing splines (NCSS-df-6) and for P-splines (PS-lambda-0.316). The function traitSmooth is used for the comparison, probeSmooths could be called directly instead. The PS splines with  $\lambda = 0.316$  are chosen because they tend to smooth a little less than the NCSS splines, especially before DAP 26.

```
suppressWarnings(
  traitSmooth(data = smth.dat,
              response = "WU", response.smoothed = "sWU",
              individuals = "Snapshot.ID.Tag", times = "DAP",
              trait.types = "response",
              smoothing.args = args4smoothing(smoothing.methods = c("dir", "dir"),
                                               spline.types = c("N", "P"),
                                               df = c(6, NA), lambdas = c(NA, 0.316),
                                               smoothing.segments = DAP.segs,
                                               combinations = "parallel"),
              chosen.smooth.args = NULL,
              profile.plot.args =
                args4profile_plot(plots.by = NULL,
                                  facet.x = tune.fac, facet.y = "AMF",
                                  colour.column = "AMF",
                                  facet.labeller = labeller(AMF = labelAMF)),
              meddevn.plot.args =
                args4meddevn_plot(plots.by = NULL, plots.group = tune.fac,
                                  facet.x = ".", facet.y = "AMF",
                                  facet.labeller = labeller(AMF = labelAMF))))
```

### Produce the plots for the chosen smooth and add it to longi.dat

Here traitSmooth is used to fit the two smooths specified in spar.schemes in the previous step and the chosen.splines argument is set for the fit using PS splines with  $\lambda = 0.316$ .

# Step IV: Identify potential outliers and remove if justified

A plant was identified as slow growing. Even though its pot had been inoculated with AMF, it had low AMF root colonization and a random mutated shoot phenotype, which could explain why its behaviour was consistent with a plant that was not inoculated with AMF. We omit the it from further analysis.

### Omit responses for the outlier plant

The outlier plant is omitted by setting all of its responses to NA, i.e. the metadata for the plant is retained in longi.dat.

# Step V: Extract single-valued traits for each individual

In this step, traits that have a single-value for each plant (cart) are created from the smoothed PSA (sPSA) and the smoothed WU (sWU), along with the derived traits sPSA AGR, sPSA RGR, sWUR (smoothed Water Use Rate) and sPSA.sWUI (smoothed Water Use Index with sPSA as the numerator). The single-valued traits are based on a set of endpoints for DAP intervals. The DAP endpoints that were chosen, as described by Brien et al. (2020), are 18, 22, 27, 33, 39, 43 and 51. Corresponding to these endpoints are the time intervals DAP 18–22, DAP 22–27, DAP 27–33, DAP 33–39, DAP 39–43 and DAP 43–51. Based on these endpoints and intervals, the following single-valued traits are to be computed:

- 1. single-times traits: sPSA for each DAP
- 2. growth rates for a time interval: sPSA AGR and sPSA RGR for the six intervals.
- 3. water use traits for a time interval: sWU, sWUR and sPSA.sWUI for the six intervals.
- 4. total for the overall imaging period: sWU for DAP 18–51.
- 5. maximum for the overall imaging period: maximum of the sPSA AGR during DAP 18–51 and the DAP on which it occurred.

# Step VI: Save to files

Save data files as csv, Excel and rda files

```
save(longi.dat, file="longi.dat.rda")
write.csv(longi.dat, "longi.dat.csv", row.names = F)
WriteXLS("longi.dat", ExcelFileName = "longi.dat.xlsx", SheetNames = "longi.dat",
        row.names = FALSE, BoldHeaderRow = TRUE, AdjWidth = TRUE, FreezeRow = 1)
save(indv.dat, file="indv.dat.rda")
write.csv(indv.dat, "indv.dat.csv", row.names = F)
WriteXLS("indv.dat", ExcelFileName = "indv.dat.xlsx", SheetNames = "indv.dat",
        row.names = FALSE, BoldHeaderRow = TRUE, AdjWidth = TRUE, FreezeRow = 1)
```

Save the workspace image

save.image("Tomato.RData")
