

Package ‘runner’

April 22, 2021

Title Running Operations for Vectors

Type Package

Version 0.4.0

Depends R (>= 3.0)

Language en-US

Encoding UTF-8

Maintainer Dawid Kałedkowski <dawid.kaledkowski@gmail.com>

Description Lightweight library for rolling windows operations. Package enables full control over the window length, window lag and a time indices. With a runner one can apply any R function on a rolling windows. The package eases work with equally and unequally spaced time series.

License GPL (>= 2)

BugReports <https://github.com/gogonzo/runner/issues>

LinkingTo Rcpp

Imports methods, parallel, Rcpp

Suggests knitr, rmarkdown, tinytest

RoxygenNote 7.1.1

VignetteBuilder knitr

NeedsCompilation yes

fill_run	<i>Fill NA with previous non-NA element</i>
----------	---------------------------------------------

Description

Fill NA with last non-NA element.

Usage

```
fill_run(x, run_for_first = FALSE, only_within = FALSE)
```

Arguments

x	(vector, data.frame, matrix, xts) Input in runner custom function f.
run_for_first	If first elements are filled with NA, run_for_first = TRUE allows to fill all initial NA with nearest non-NA value. By default run_for_first = TRUE
only_within	NA are replaced only if previous and next non-NA values are the same. By default only_within = TRUE

Value

vector - x containing all x elements with NA replaced with previous non-NA element.

Examples

```
fill_run(c(NA, NA, 1:10, NA, NA), run_for_first = TRUE)
fill_run(c(NA, NA, 1:10, NA, NA), run_for_first = TRUE)
fill_run(c(NA, NA, 1:10, NA, NA), run_for_first = FALSE)
fill_run(c(NA, NA, 1, 2, NA, NA, 2, 2, NA, NA, 1, NA, NA), run_for_first = TRUE, only_within = TRUE)
```

k_by	<i>Converts k and lag from time-unit-interval to int</i>
------	----------------------------------------------------------

Description

Converts k and lag from time-unit-interval to int

Usage

```
k_by(k, idx, param)
```

Arguments

k	(integer vector or single value) Denoting size of the running window. If k is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element. One can also specify k in the same way as by argument in <code>seq.POSIXt</code> . See 'Specifying time-intervals' in details section.
idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.
param	name of the parameter to be printed in error message

Examples

```
k <- "1 month"
idx <- seq(
  as.POSIXct("2019-01-01 03:02:01"),
  as.POSIXct("2020-01-01 03:02:01"),
  by = "month"
)
k_difftime <- runner::k_by(k, idx, param = "k")
idx - k_difftime
```

lag_run	<i>Lag dependent on variable</i>
---------	----------------------------------

Description

Vector of input lagged along integer vector

Usage

```
lag_run(x, lag = 1L, idx = integer(0), nearest = FALSE)
```

Arguments

x	(vector, data.frame, matrix, xts) Input in runner custom function f.
lag	(integer vector or single value) Denoting window lag. If lag is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward. One can also specify lag in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.
nearest	logical single value. Applied when idx is used, then nearest = FALSE returns observation lagged exactly by the specified number of "periods". When nearest = TRUE function returns latest observation within lag window.

Examples

```
lag_run(1:10, lag = 3)
lag_run(letters[1:10], lag = -2, idx = c(1, 1, 1, 2, 3, 4, 6, 7, 8, 10))
lag_run(letters[1:10], lag = 2, idx = c(1, 1, 1, 2, 3, 4, 6, 7, 8, 10), nearest = TRUE)
```

length_run	<i>Length of running windows</i>
------------	----------------------------------

Description

Number of elements in k-long window calculated on idx vector. If idx is an 'as.integer(date)' vector, then k=number of days in window - then the result is number of observations within k days window.

Usage

```
length_run(k = integer(1), lag = integer(1), idx = integer(0))
```

Arguments

k	(integer vector or single value) Denoting size of the running window. If k is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element. One can also specify k in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
---	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

lag	(integer vector or single value) Denoting window lag. If lag is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward. One can also specify lag in the same way as by argument in <code>seq.POSIXt</code> . See 'Specifying time-intervals' in details section.
idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.

Examples

```
length_run(k = 3, idx = c(1, 2, 2, 4, 5, 5, 5, 5, 5, 5))
```

max_run	<i>Running maximum</i>
---------	------------------------

Description

min_run calculates running max on given x numeric vector, specified k window size.

Usage

```
max_run(  
  x,  
  k = integer(0),  
  lag = integer(1),  
  idx = integer(0),  
  at = integer(0),  
  na_rm = TRUE,  
  na_pad = FALSE  
)
```

Arguments

x	(vector, data.frame, matrix, xts) Input in runner custom function f.
k	(integer vector or single value) Denoting size of the running window. If k is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element. One can also specify k in the same way as by argument in <code>seq.POSIXt</code> . See 'Specifying time-intervals' in details section.

lag	(integer vector or single value) Denoting window lag. If lag is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward. One can also specify lag in the same way as by argument in <code>seq.POSIXt</code> . See 'Specifying time-intervals' in details section.
idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.
at	(integer, Date, POSIXt, character vector) Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at. Can be also POSIXt sequence increment used in at argument in <code>seq.POSIXt</code> . See 'Specifying time-intervals' in details section.
na_rm	logical single value (default na_rm = TRUE) - if TRUE sum is calculating excluding NA.
na_pad	(logical single value) Whether incomplete window should return NA (if na_pad = TRUE) Incomplete window is when some parts of the window are out of range.

Value

max numeric vector of length equals length of x.

Examples

```
set.seed(11)
x1 <- sample( c(1,2,3), 15, replace=TRUE)
x2 <- sample( c(NA,1,2,3), 15, replace=TRUE)
k <- sample( 1:4, 15, replace=TRUE)
max_run(x1) # simple cumulative maximum
max_run(x2, na_rm = TRUE) # cumulative maximum with removing NA.
max_run(x2, na_rm = TRUE, k=4) # maximum in 4-element window
max_run(x2, na_rm = FALSE, k=k) # maximum in varying k window size
```

mean_run

Running mean

Description

Running mean in specified window of numeric vector.

Usage

```
mean_run(
  x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_rm = TRUE,
  na_pad = FALSE
)
```

Arguments

<code>x</code>	numeric vector which running function is calculated on
<code>k</code>	(integer' vector or single value) Denoting size of the running window. If <code>k</code> is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element.
<code>lag</code>	(integer vector or single value) Denoting window lag. If <code>lag</code> is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward.
<code>idx</code>	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default <code>idx</code> is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then <code>k</code> and <code>lag</code> are depending on <code>idx</code> . Length of <code>idx</code> have to be equal of length <code>x</code> .
<code>at</code>	(integer, Date, POSIXt, character vector) Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at.
<code>na_rm</code>	logical single value (default <code>na_rm = TRUE</code>) - if <code>TRUE</code> sum is calculating excluding NA.
<code>na_pad</code>	(logical single value) Whether incomplete window should return NA (if <code>na_pad = TRUE</code>) Incomplete window is when some parts of the window are out of range.

Value

mean numeric vector of length equals length of `x`.

Examples

```
set.seed(11)
x1 <- rnorm(15)
x2 <- sample(c(rep(NA,5), rnorm(15)), 15, replace = TRUE)
k <- sample(1:15, 15, replace = TRUE)
mean_run(x1)
```

```
mean_run(x2, na_rm = TRUE)
mean_run(x2, na_rm = FALSE )
mean_run(x2, na_rm = TRUE, k=4)
```

minmax_run	<i>Running min/max</i>
------------	------------------------

Description

min_run calculates running minimum-maximum on given x numeric vector, specified k window size.

Usage

```
minmax_run(x, metric = "min", na_rm = TRUE)
```

Arguments

x	(vector, data.frame, matrix, xts) Input in runner custom function f.
metric	character what to return, minimum or maximum
na_rm	logical single value (default na_rm = TRUE) - if TRUE sum is calculating excluding NA.

Value

list.

min_run	<i>Running minimum</i>
---------	------------------------

Description

min_run calculates running min on given x numeric vector, specified k window size.

Usage

```
min_run(
  x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_rm = TRUE,
  na_pad = FALSE
)
```

Arguments

x	(vector, data.frame, matrix, xts) Input in runner custom function f.
k	(integer vector or single value) Denoting size of the running window. If k is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element. One can also specify k in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
lag	(integer vector or single value) Denoting window lag. If lag is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward. One can also specify lag in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.
at	(integer, Date, POSIXt, character vector) Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at. Can be also POSIXt sequence increment used in at argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
na_rm	logical single value (default <code>na_rm = TRUE</code>) - if TRUE sum is calculating excluding NA.
na_pad	(logical single value) Whether incomplete window should return NA (if <code>na_pad = TRUE</code>) Incomplete window is when some parts of the window are out of range.

Value

min numeric vector of length equals length of x.

Examples

```
set.seed(11)
x1 <- sample(c(1, 2, 3), 15, replace = TRUE)
x2 <- sample(c(NA, 1, 2, 3), 15, replace = TRUE)
k <- sample(1:4, 15, replace = TRUE)
min_run(x1)
min_run(x2, na_rm = TRUE)
min_run(x2, na_rm = TRUE, k = 4)
min_run(x2, na_rm = FALSE, k = k)
```

reformat_k	<i>Formats time-unit-interval to valid for runner</i>
------------	-------------------------------------------------------

Description

Formats time-unit-interval to valid for runner. User specifies k as positive number but this means that this interval needs to be subtracted from idx - because windows length extends window backwards in time. The same situation for lag.

Usage

```
reformat_k(k, only_positive = TRUE)
```

Arguments

k (k or lag) object from runner to be formatted
 only_positive for k is TRUE, for lag is FALSE

Examples

```
runner::reformat_k("1 days")
runner::reformat_k("day")
runner::reformat_k("10 days")
runner::reformat_k("-10 days", only_positive = FALSE)
runner::reformat_k(c("-10 days", "2 months"), only_positive = FALSE)
```

runner	<i>Apply running function</i>
--------	-------------------------------

Description

Applies custom function on running windows.

Usage

```
runner(
  x,
  f = function(x) x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_pad = FALSE,
  type,
  simplify = TRUE,
  cl = NULL,
```

```
    ...
  )

## Default S3 method:
runner(
  x,
  f = function(x) x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_pad = FALSE,
  type,
  simplify = TRUE,
  cl = NULL,
  ...
)

## S3 method for class 'data.frame'
runner(
  x,
  f = function(x) x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_pad = FALSE,
  type,
  simplify = TRUE,
  cl = NULL,
  ...
)

## S3 method for class 'grouped_df'
runner(
  x,
  f = function(x) x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_pad = FALSE,
  type,
  simplify = TRUE,
  cl = NULL,
  ...
)
```

```

## S3 method for class 'matrix'
runner(
  x,
  f = function(x) x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_pad = FALSE,
  type,
  simplify = TRUE,
  cl = NULL,
  ...
)

## S3 method for class 'xts'
runner(
  x,
  f = function(x) x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_pad = FALSE,
  type,
  simplify = TRUE,
  cl = NULL,
  ...
)

```

Arguments

<code>x</code>	(vector, data.frame, matrix, xts) Input in runner custom function <code>f</code> .
<code>f</code>	(function) Applied on windows created from <code>x</code> . This function is meant to summarize windows and create single element for each window, but one can also specify function which return multiple elements (runner output will be a list). By default runner returns windows as is (<code>f = function(x)</code>).
<code>k</code>	(integer vector or single value) Denoting size of the running window. If <code>k</code> is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element. One can also specify <code>k</code> in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
<code>lag</code>	(integer vector or single value) Denoting window lag. If <code>lag</code> is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward. One can also specify <code>lag</code>

in the same way as by argument in [seq.POSIXt](#). See 'Specifying time-intervals' in details section.

idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.
at	(integer, Date, POSIXt, character vector) Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at. Can be also POSIXt sequence increment used in at argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
na_pad	(logical single value) Whether incomplete window should return NA (if na_pad = TRUE) Incomplete window is when some parts of the window are out of range.
type	(defunct) argument defunct from version 0.4.0. Use <code>simplify</code> instead.
simplify	(logical or character value) should the result be simplified to a vector, matrix or higher dimensional array if possible. The default value, <code>simplify = TRUE</code> , returns a vector or matrix if appropriate, whereas if <code>simplify = "array"</code> the result may be an array of "rank" (<code>=length(dim(.))</code>) one higher than the result of output from the function <code>f</code> for each window. Consequences of <code>simplify</code> in <code>runner</code> are identical to <code>sapply</code> .
cl	(cluster) <i>experimental</i> Create and pass the cluster to the <code>runner</code> function to run each window calculation in parallel. See makeCluster in details.
...	(optional) other arguments passed to the function <code>f</code> .

Details

Function can apply any R function on running windows defined by `x`, `k`, `lag`, `idx` and `at`. Running window can be calculated on several ways:

- **Cumulative windows**

applied when user doesn't specify `k` argument or specify `k = length(x)`, this would mean that `k` is equal to number of available elements

- **Constant sliding windows**

applied when user specify k as constant value keeping idx and at unspecified. lag argument shifts windows left ($\text{lag} > 0$) or right ($\text{lag} < 0$).

- **Windows depending on date**

If one specifies idx this would mean that output windows size might change in size because of unequally spaced indexes. For example 5-period window is different than 5-element window, because 5-period window might contain any number of observation (7-day mean is not the same as 7-element mean)

- **Window at specific indices**

runner by default returns vector of the same size as x unless one specifies at argument. Each element of at is an index on which runner calculates function - which means that output of the runner is now of length equal to at. Note that one can change index of x by specifying idx. Illustration below shows output of runner for at = c(18, 27, 45, 31) which gives windows in ranges enclosed in square brackets. Range for at = 27 is [22, 26] which is not available in current indices.

```

k = 5, lag = 1, at = c(18, 27, 48, 31)
  4  6  7 13 17 18 18 21 27 31 37 42 44 47 48
18 [13, 17]
27 [22, 26]
48 [43, 47]
31 [26, 30]

```

Specifying time-intervals:

at can also be specified as interval of the output defined by `at = "<increment>"` which results in indices sequence defined by `seq.POSIXt(min(idx), max(idx), by = "<increment>")`. Increment of sequence is the same as in `seq.POSIXt` function. It's worth noting that increment interval can't be more frequent than interval of `idx` - for Date the most frequent time-unit is a "day", for POSIXt a sec.

k and lag can also be specified as using time sequence increment. Available time units are "sec", "min", "hour", "day", "DSTday", "week", "month", "quarter" or "year". To increment by number of units one can also specify `<number> <unit>s` for example `lag = "-2 days"`, `k = "5 weeks"`.

Setting k and lag as a sequence increment can be also a vector can be a vector which allows to stretch and lag/lead each window freely on in time (on indices).

Parallel computing:

Beware that executing R call in parallel not always have the edge over single-thread even if the `cl <-registerCluster(detectCores())` was specified before.

Parallel windows are executed in the independent environment, which means that objects other than function arguments needs to be copied to the parallel environment using `clusterExport`. For example using `f = function(x) x + y + z` will result in error as `clusterExport(cl, varlist = c("y", "z"))` needs to be called before.

Value

vector with aggregated values for each window. Length of output is the same as `length(x)` or `length(at)` if specified. Type of the output depends on the output from a function `f`.

Examples

```

# runner returns windows as is by default
runner(1:10)

# mean on k = 3 elements windows
runner(1:10, f = mean, k = 3)

# mean on k = 3 elements windows with different specification
runner(1:10, k = 3, f = function(x) mean(x, na.rm = TRUE))

# concatenate two columns
runner(
  data.frame(
    a = letters[1:10],

```

```

    b = 1:10
  ),
  f = function(x) paste(paste0(x$a, x$b), collapse = "+")
)

# concatenate two columns with additional argument
runner(
  data.frame(
    a = letters[1:10],
    b = 1:10
  ),
  f = function(x, xxx) {
    paste(paste0(x$a, xxx, x$b), collapse = " + ")
  },
  xxx = "...")
)

# number of unique values in each window (varying window size)
runner(letters[1:10],
      k = c(1, 2, 2, 4, 5, 5, 5, 5, 5, 5),
      f = function(x) length(unique(x)))

# concatenate only on selected windows index
runner(letters[1:10],
      f = function(x) paste(x, collapse = "-"),
      at = c(1, 5, 8))

# 5 days mean
idx <- c(4, 6, 7, 13, 17, 18, 18, 21, 27, 31, 37, 42, 44, 47, 48)
runner::runner(
  x = idx,
  k = "5 days",
  lag = 1,
  idx = Sys.Date() + idx,
  f = function(x) mean(x)
)

# 5 days mean at 4-indices
runner::runner(
  x = 1:15,
  k = 5,
  lag = 1,
  idx = idx,
  at = c(18, 27, 48, 31),
  f = mean
)

# runner with data.frame
df <- data.frame(
  a = 1:13,
  b = 1:13 + rnorm(13, sd = 5),
  idx = seq(Sys.Date(), Sys.Date() + 365, by = "1 month")
)

```

```
runner(  
  x = df,  
  idx = "idx",  
  at = "6 months",  
  f = function(x) {  
    cor(x$a, x$b)  
  }  
)  
  
# parallel computing  
library(parallel)  
data <- data.frame(  
  a = runif(100),  
  b = runif(100),  
  idx = cumsum(sample(rpois(100, 5)))  
)  
const <- 0  
cl <- makeCluster(1)  
clusterExport(cl, "const", envir = environment())  
  
runner(  
  x = data,  
  k = 10,  
  f = function(x) {  
    cor(x$a, x$b) + const  
  },  
  idx = "idx",  
  cl = cl  
)  
stopCluster(cl)  
  
# runner with matrix  
data <- matrix(data = runif(100, 0, 1), nrow = 20, ncol = 5)  
runner(  
  x = data,  
  f = function(x) {  
    tryCatch(  
      cor(x),  
      error = function(e) NA  
    )  
  })
```

run_by

Set window parameters

Description

Set window parameters for [runner](#). This function sets the attributes to `x` (only `data.frame`) object and saves user effort to specify window parameters in further multiple [runner](#) calls.

Usage

```
run_by(x, idx, k, lag, na_pad, at)
```

Arguments

x (vector, data.frame, matrix, xts)
Input in runner custom function *f*.

idx (integer, Date, POSIXt)
Optional integer vector containing sorted (ascending) index of observation. By default *idx* is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then *k* and *lag* are depending on *idx*. Length of *idx* have to be equal of length *x*.

k (integer vector or single value)
Denoting size of the running window. If *k* is a single value then window size is constant for all elements, otherwise if `length(k) == length(x)` different window size for each element. One can also specify *k* in the same way as by argument in [seq.POSIXt](#). See 'Specifying time-intervals' in details section.

lag (integer vector or single value)
Denoting window lag. If *lag* is a single value then window lag is constant for all elements, otherwise if `length(lag) == length(x)` different window size for each element. Negative value shifts window forward. One can also specify *lag* in the same way as by argument in [seq.POSIXt](#). See 'Specifying time-intervals' in details section.

na_pad (logical single value)
Whether incomplete window should return NA (if `na_pad = TRUE`) Incomplete window is when some parts of the window are out of range.

at (integer, Date, POSIXt, character vector)
Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at. Can be also POSIXt sequence increment used in *at* argument in [seq.POSIXt](#). See 'Specifying time-intervals' in details section.

Value

x object which [runner](#) can be executed on.

Examples

```
## Not run:
library(dplyr)

data <- data.frame(
  index = c(2, 3, 3, 4, 5, 8, 10, 10, 13, 15),
  a = rep(c("a", "b"), each = 5),
  b = 1:10
)

data %>%
```

```

group_by(a) %>%
run_by(idx = "index", k = 5) %>%
mutate(
  c = runner(
    x = .,
    f = function(x) {
      paste(x$b, collapse = ">")
    }
  ),
  d = runner(
    x = .,
    f = function(x) {
      sum(x$b)
    }
  )
)

## End(Not run)

```

seq_at	<i>Creates sequence for at as time-unit-interval</i>
--------	------------------------------------------------------

Description

Creates sequence for at as time-unit-interval

Usage

```
seq_at(at, idx)
```

Arguments

at	object from runner
idx	object from runner

streak_run	<i>Running streak length</i>
------------	------------------------------

Description

Calculates running series of consecutive elements

Usage

```

streak_run(
  x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_rm = TRUE,
  na_pad = FALSE
)

```

Arguments

x	any type vector which running function is calculated on
k	(integer vector or single value) Denoting size of the running window. If k is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element. One can also specify k in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
lag	(integer vector or single value) Denoting window lag. If lag is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward. One can also specify lag in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.
at	(integer, Date, POSIXt, character vector) Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at. Can be also POSIXt sequence increment used in at argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
na_rm	logical single value (default na_rm = TRUE) - if TRUE sum is calculating excluding NA.
na_pad	(logical single value) Whether incomplete window should return NA (if na_pad = TRUE) Incomplete window is when some parts of the window are out of range.

Value

streak [numeric] vector of length equals length of x containing number of consecutive occurrences.

Examples

```

set.seed(11)
x1 <- sample(c("a","b"), 15, replace = TRUE)
x2 <- sample(c(NA_character_, "a", "b"), 15, replace = TRUE)
k <- sample(1:4, 15, replace = TRUE)
streak_run(x1) # simple streak run
streak_run(x1, k = 2) # streak run within 2-element window
streak_run(x2, na_pad = TRUE, k = 3) # streak run within k=3 with padding NA
streak_run(x1, k = k) # streak run within varying window size specified by vector k

```

sum_run

Running sum

Description

Running sum in specified window of numeric vector.

Usage

```

sum_run(
  x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_rm = TRUE,
  na_pad = FALSE
)

```

Arguments

x	numeric vector which running function is calculated on
k	(integer ⁺ vector or single value) Denoting size of the running window. If k is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element.
lag	(integer vector or single value) Denoting window lag. If lag is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward.
idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.

at	(integer, Date, POSIXt, character vector) Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at.
na_rm	logical single value (default na_rm = TRUE) - if TRUE sum is calculating excluding NA.
na_pad	(logical single value) Whether incomplete window should return NA (if na_pad = TRUE) Incomplete window is when some parts of the window are out of range.

Value

sum code vector of length equals length of x.

Examples

```
set.seed(11)
x1 <- rnorm(15)
x2 <- sample(c(rep(NA, 5), rnorm(15)), 15, replace = TRUE)
k <- sample(1:15, 15, replace = TRUE)
sum_run(x1)
sum_run(x2, na_rm = TRUE)
sum_run(x2, na_rm = FALSE)
sum_run(x2, na_rm = TRUE, k = 4)
```

this_group	<i>Access group data in mutate</i>
------------	------------------------------------

Description

Access group data in `dplyr::mutate` after `dplyr::group_by`. Function created because data available in `dplyr::group_by %>% mutate` scheme is not filtered by group - in `mutate` function . is still initial dataset. This function creates data.frame using `dplyr::groups` information.

Usage

```
this_group(x)
```

Arguments

x	(data.frame) object which can be <code>grouped_df</code> in special case.
---	------------------------------------------------------------------------------

Value

data.frame filtered by current `dplyr::groups()`

which_run	<i>Running which</i>
-----------	----------------------

Description

`min_run` calculates running which - returns index of element where `x == TRUE`.

Usage

```
which_run(
  x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  which = "last",
  na_rm = TRUE,
  na_pad = FALSE
)
```

Arguments

<code>x</code>	(vector, data.frame, matrix, xts) Input in runner custom function <code>f</code> .
<code>k</code>	(integer vector or single value) Denoting size of the running window. If <code>k</code> is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element. One can also specify <code>k</code> in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
<code>lag</code>	(integer vector or single value) Denoting window lag. If <code>lag</code> is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward. One can also specify <code>lag</code> in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
<code>idx</code>	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default <code>idx</code> is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then <code>k</code> and <code>lag</code> are depending on <code>idx</code> . Length of <code>idx</code> have to be equal of length <code>x</code> .
<code>at</code>	(integer, Date, POSIXt, character vector) Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at. Can be also POSIXt sequence increment used in <code>at</code> argument in seq.POSIXt . See 'Specifying time-intervals' in details section.

which	character value "first" or "last" denoting if the first or last TRUE index is returned from the window.
na_rm	logical single value (default na_rm = TRUE) - if TRUE sum is calculating excluding NA.
na_pad	(logical single value) Whether incomplete window should return NA (if na_pad = TRUE) Incomplete window is when some parts of the window are out of range.

Value

integer vector of indexes of the same length as x.

Examples

```
set.seed(11)
x1 <- sample(c(1, 2, 3), 15, replace = TRUE)
x2 <- sample(c(NA, 1, 2, 3), 15, replace = TRUE)
k <- sample(1:4, 15, replace = TRUE)
which_run(x1)
which_run(x2, na_rm = TRUE)
which_run(x2, na_rm = TRUE, k = 4)
which_run(x2, na_rm = FALSE, k = k)
```

window_run	<i>List of running windows</i>
------------	--------------------------------

Description

Creates list of windows with given arguments settings. Length of output list is equal

Usage

```
window_run(
  x,
  k = integer(0),
  lag = integer(1),
  idx = integer(0),
  at = integer(0),
  na_pad = FALSE
)
```

Arguments

x (vector, data.frame, matrix, xts)
Input in runner custom function f.

k	(integer vector or single value) Denoting size of the running window. If k is a single value then window size is constant for all elements, otherwise if <code>length(k) == length(x)</code> different window size for each element. One can also specify k in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
lag	(integer vector or single value) Denoting window lag. If lag is a single value then window lag is constant for all elements, otherwise if <code>length(lag) == length(x)</code> different window size for each element. Negative value shifts window forward. One can also specify lag in the same way as by argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
idx	(integer, Date, POSIXt) Optional integer vector containing sorted (ascending) index of observation. By default idx is index incremented by one. User can provide index with varying increment and with duplicated values. If specified then k and lag are depending on idx. Length of idx have to be equal of length x.
at	(integer, Date, POSIXt, character vector) Vector of any size and any value defining output data points. Values of the vector defines the indexes which data is computed at. Can be also POSIXt sequence increment used in at argument in seq.POSIXt . See 'Specifying time-intervals' in details section.
na_pad	(logical single value) Whether incomplete window should return NA (if <code>na_pad = TRUE</code>) Incomplete window is when some parts of the window are out of range.

Value

list of vectors (windows). Length of list is the same as `length(x)` or `length(at)` if specified, and length of each window is defined by k (unless window is out of range).

Examples

```
window_run(1:10, k = 3, lag = -1)
window_run(letters[1:10], k = c(1, 2, 2, 4, 5, 5, 5, 5, 5, 5))
```
